Biography

- **Definition:** A connectome—a matrix describing the connectivity between any pair of brain regions
 - Is a popular approach in neuroscience to study the brain's functional organization.
- How to make: They are created by parcellating the brain into distinct areas using an atlas and estimating the connections between these regions.
- Applications: To study individual differences in brain function, associating brain and behavior, and understanding brain alterations in neuropsychiatric disorders.

Functional Connectivity

Widely used in neuroscience to understand the functional organization of the brain.

- 1. What are a connectomes
- 2. How to make functional connectivity
- 3. Applications in neuroscience

 Steps motion correction, skull stripping, registering to common space, and registering to the anatomical image are common steps before parcellations.

Mass Mulivariate Edge-wise Analysis

Mass Univariate Edge-wise Analysis

- The need for an atlas to create a connectome hinders comparisons across studies and replication and generalization efforts.
- Different atlases divide the brain into different regions of varying size and topology.
- Thus connectomes created from different atlases are not directly comparable.
 - Further, several atlases exist with no gold standards, and more are being developed yearly.

Limitations

- The need for an atlas to create a connectome hinders generalization efforts.
- 1. The need for an atlas to create connectomics
- 2. Multiple atlases are available

Example 1: In predictive modeling, the feature \bullet space between train and test should match:

A

- It's impractical to train a model on A and test on B: $Y = X^T \beta + \epsilon.$
- Other techniques include meta-learning, transfer learning, and federated learning.

Theoretical Concerns

Examples from predictive modeling and explanatory analysis

- 1. Predictive modeling
- 2. Explanatory analysis

• Generalizability:

- Currently, no solutions exist to extend previous results to a connectome generated from a different atlas.
- This prevents these datasets from being combined without reprocessing data.

• Storage concerns:

 Smaller labs might not have the resources to store and reprocess these data from scratch.

• Privacy concerns:

- Due to privacy concerns of being able to identify a participant based on unprocessed data, some datasets are only released as fully processed connectomes.
- Critically, in this case, it is not possible to go to the data to create connectomes from another atlas.

Real-world challenges

Different studies have different standards and limitations

- 1. Generalizability
- 2. Storage concerns
- 3. Privacy concerns

Our solution: dataset harmonization

Estimating connectomes in a missing form

- 1. Time series-based approach
- 2. Transforming distribution of ROIs across atlases

P(observation | True Coin) $\overline{q_1^{N_H}} q_2^{N_T}$ *P*(observation | Coin 2)

Coin 2 Heads

Tails

An overview on information theory **Classical methods to** compare distributions

- 1. KL divergence
- 2. JS divergence
- 3. Having the same number of supports is equired

$$= D_{KL}(p \mid \mid q) = \sum_{x \in \mathcal{X}} p(x) \log\left(\frac{p(x)}{q(x)}\right)$$

$$\left(\frac{N_H}{N_T}\right)^{\frac{1}{N}}$$

$$-\frac{1}{N}\log q_2^{N_T}$$

$$\frac{1}{N_1}\log q_2^{N_1}$$

Kullback–Leibler divergence

Measures exactly the same thing

- 1. Log properties, product to addition, division to subtraction
- 2. How likely q(x) would generate samples from p(x)

Jensen-Shannon divergence = $\frac{1}{2}D_{KL}\left(p \mid \mid \frac{p+q}{2}\right) + \frac{1}{2}D_{KL}\left(p \mid \mid \frac{p+q}{2}\right)$

squared Hellinger distance = $2\sum \left(\sqrt{p(x)} - \sqrt{q(x)}\right)^2$

$$\alpha - \text{divergence} = \frac{4}{1 - \alpha} \left(1 - \sum p(x)^{\frac{1 - \alpha}{2}} q(x)^{\frac{1 + \alpha}{2}} \right)$$

chi-squared divergence =
$$\sum_{x} \frac{(p(x) - q(x))^{2}}{p(x)}$$

What if p and q have different number of classes?

Jensen-Shannon divergence

A symmetric version of KL-divergence

- 1. Symmetric
- 2. Other divergence methods

Background

Optimal transport

A mapping between locations x and y

$$T: \{x_1, \ldots, x_n\} \to \{y_1, \ldots, y_n\}$$

must verify

$$\mathbf{b}_j = \sum_{i:T(x_i) = y_j} a_i$$

The only criterion here is to make sure we transfer all mass into some location y_i

Background

Optimal transport

This map should minimize some transportation cost, which is parameterized by a cost function C

$$\min_{T} \left\{ \sum_{i} C(x_{i}, T(x_{i})) : T_{\sharp} \alpha = \beta \right\},\$$

Background

Optimal transport

Kantorovich [1942]

Push-forward of measures

Pull-back of functions

Kantorovich Relaxation [1942]

$$\mathbf{U}(\mathbf{a}, \mathbf{b}) \stackrel{\text{def.}}{=} \left\{ \mathbf{P} \in \mathbb{R}^{n \times m}_{+} : \mathbf{P} \mathbb{1}_{m} = \mathbf{a} \text{ and } \mathbf{P}^{\mathrm{T}} \mathbb{1}_{n} = \left(\sum_{j} \mathbf{P}_{i,j}\right)_{i} \in \mathbb{R}^{n} \text{ and } \mathbf{P}^{\mathrm{T}} \mathbb{1}_{n} = \left(\sum_{i} \mathbf{P}_{i,j}\right)_{j} \in \mathbb{R}^{n}$$

Admissible Couplings

Background

Optimal transport

Kantorovich [1942] Kantorovich's optimal transport problem now reads

$$\mathrm{L}_{\mathbf{C}}(\mathbf{a},\mathbf{b}) \stackrel{\mathrm{\tiny def.}}{=} \min_{\mathbf{P}\in\mathbf{U}(\mathbf{a},\mathbf{b})} \langle \mathbf{C},\,\mathbf{P}
angle \stackrel{\mathrm{\scriptstyle def.}}{=} \sum_{i,j} \mathbf{C}_{i,j} \mathbf{P}_{i,j}$$

Kantorovich Relaxation is symmetric $P \in U(a, b) \Leftrightarrow P^T \in U(b, a)$

Background

Optimal transport

Hitchcock [1941] Kantorovich [1942]

Entropy regularization: An approximation solution

$$\mathbf{L}_{\mathbf{C}}^{\varepsilon}(\mathbf{a},\mathbf{b}) \stackrel{\text{\tiny def.}}{=} \min_{\mathbf{P}\in\mathbf{U}(\mathbf{a},\mathbf{b})} \langle \mathbf{P}, \mathbf{C} \rangle - \varepsilon \mathbf{H}(\mathbf{P}).$$

Iterative solutions: Sinkhorn algorithm

$$C_a^1 = \{P, P1 = a\} \qquad C_b^2 = \{P, P1 = b\}$$
$$P^{(l+1)} = \operatorname{Proj}_{C_a^1}^{\mathsf{KL}} P(l) \qquad P^{(l+2)} = \operatorname{Proj}_{C_b^2}^{\mathsf{KL}} P(l+1)$$

$$C = \begin{pmatrix} C_{1,1} & \dots & C_{1,m} \\ \dots & & \dots \\ C_{n,1} & \dots & C_{n,m} \end{pmatrix} \in \mathbb{R}^{n \times m}$$

 $C_{i,i}$ = Euclidean distance

Cross Atlas Remapping via Optimal Transport (CAROT)

A data-driven method to measure the distance and find a policy to transform connectomes

- 1. Translating each time frame to a vector
- 2. Cost matrix
- 3. Loss function

test data point $\nu = \mu T$

What if multiple parcellations for each individual are available?

Cross Atlas Remapping via Optimal Transport (CAROT)

Test data point available in the source atlas

- 1. Applying the trained policies T
- 2. Some of large scale projects release data in multiple atlases
- 3. A need for an advance version

Cross Atlas Remapping via Optimal Transport (CAROT)

An advanced version when multiple parcellations are available

- 1. Incorporating multiple time series
- 2. Bigger cost matrix
- 3. Bigger policy

The Human Connectome project is used for training mappings, intrinsic analysis, and for some downstream analysis

 $\binom{6}{2} + 6 = 21$ transportation policies

Experiments:

Human connectome projects

- 1. Train-test split
- 2. 25% for policy training
- 3. 75% for testing
- 4. 10 fold CV

Cross-dataset analysis: We used resting-state data collected from 100 participants at the Yale School of Medicine.

This dataset included 50 females (age=33) and 50 males (age=34.9) with eight functional scans (48 minutes total).

Experiments: Yale participant

- 1. Testing generalization of policies
- 2. 50 male and 50 female Yale participant dataset

Power

25%

Shen Atlas

Experiments:

Rest-meta MDD dataset

- 1. Testing generalization of models
- 2. A dataset that is not released on Shen 268
- 3. A model that performs the best on Shen 268

- You can see that some spots are more intense than others indicating higher transformation between regions.
- This emphasizes some of the structural differences between atlases:
 - The horizontal line between Schaefer and Shen is belonging to areas that are missing in Schaefer

Policies

How does a policy look like

- 1. Topological differences are clear
- 2. Schaefer doesn't include some areas

$$C^* = \begin{pmatrix} C_{1,1} & \cdots & C_{1,m} \\ \cdots & \cdots & \cdots \\ C_{n_s,1} & \cdots & C_{n,m} \end{pmatrix} \in \mathbb{R}^{n_s \times m} \qquad C = 1 - \begin{pmatrix} \rho(U_{1,.}, N_{1,.}) \\ \cdots \\ \rho(U_{m,.}, N_{1,.}) \end{pmatrix}$$

 ρ_{U_i,N_i} = Spearman correlation $C_{i,i}$ = Euclidean distance

$$\begin{array}{ccc} & \rho(U_{1,.}, N_{n,.}) \\ & \ddots & & \\ & \ddots & \\ & & \rho(U_{m,.}, N_{n,.}) \end{array} \end{array} \in \mathbb{R}^{m \times n}$$

What should we choose as a cost matrix?

Functional distance vs Euclidean distance

- 1. Euclidean distance
- 2. Functional distance

Reconstructed connectomes give similar aging results as the original connectomes. (Top) the nodes with the largest number of edges are significantly associated with age for original connectomes from the HCP using Shen. (bottom) reconstructed Shen connectomes (r=0.61)

- The correlation as a function of k is linearly increasing.
- There are differences among various runs and targets:
 - Similar atlases reproduced more similar connectomes
- We can predict behavior (e.g., fluid intelligence) and can identify individuals across different runs.

Experimental results

HCP dataset, resting scan connectomes

- 1. Intrinsic evaluation; correlation with original counterparts
- 2. Downstream analysis, results on predicting IQ
- 3. Fingerprinting, two resting sessions

- We investigated if CAROT mappings trained in one dataset generalize to other datasets.
- We applied the mappings trained on HCP and reconstructed connectomes using the Yale dataset using these mappings.
- Spearman's rank correlation between the upper triangles of the connectomes was used to assess the similarity between the reconstructed and original connectomes.

Real-world example

Testing a model on Rest-meta MDD

- 1. Generalization on Yale participant
- 2. Sex classification on Rest-meta MDD

- In this evaluation, we generalize a sex classification model on Yale dataset:
 - The REST-Meta-MDD dataset (Yan et al., 2016) only provides preprocessed timeseries data from the Dosenbach, Power, and Craddock atlases.
- Overall, the sex classification model demonstrated significant classification accuracy (Accuracy=60.5%; Naive model accuracy=50%;).
- Next, the sex classification model performed significantly better than chance in the REST-Meta-MDD dataset when using the reconstructed connectomes.

Real-world example

Testing a model on Rest-meta MDD

- 1. Generalization on Yale participant
- 2. Sex classification on Rest-meta MDD

Software **GitHub and live demo**

- 1. Live demo for some atlases
- 2. GitHub repository for all types of data

- In sum, CAROT allows a connectome generated based on one atlas to be directly transformed into a connectome based on another without needing raw data.
- These reconstructed connectomes are similar to and, in downstream analyses, behave like the original connectomes created from the raw data.
- Using CAROT on preprocessed open-source data will increase its utility, accelerate the use of big data, and help make a generalization and replication efforts easier.

Summary

CAROT encourages open science in connectomics

- 1. CAROT helps overcome multiple atlas problem
- 2. CAROT brings good quality
- 3. Policies are generalizable over datasets
